CS550 - Advanced OS Fall 2020 Amit Nikam A20470263 anikam@hawk.iit.edu

## **EVALUATION REPORT**

## 1) One client to the server connection:

Establishing a successful server and client connection by defining communication protocol was the first challenge in implementing multithreaded client and server.

For this test, my client was able to connect to the server and download a .jpg format image of the size 48422 Bytes in just 0.0022 seconds.

## 2) 8 clients connected to the server:

The next step was to implement a server which can handle multiple clients at the same time. To achieve this, threading was implemented on the server. Each connection to the server is handled through a handler which is threaded. This way multiple connections are handled at the same time.

For 8 clients downloading the same .jpg image file:

- Average Transfer Times were 0.0045925 seconds
- Average Downloads = 1.125
- Total Failed Downloads = 1

It is observed that the transfer time doubled i.e. transfer speed was halved compared to case 1.

## 3) Multiple clients downloading multiple files:

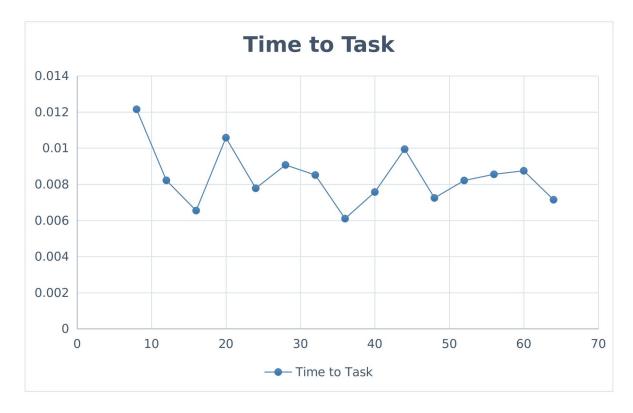

For this evaluation, 3 files of which 2 are images and 1 is text of sizes 28794, 48422 and 231 Bytes were used. The same process of downloading these three files was repeated for incrementing number of client connections.

The following table is based on the implementation outcomes

| #<br>Client | Average Transfer<br>Time per File | Average Downloads | Average Total Time each client spent downloading |
|-------------|-----------------------------------|-------------------|--|
| 8           | 0.002700057                       | 4.5               | 0.012150258                                      |
| 12          | 0.002464616                       | 3.33333333        | 0.008215388                                      |
| 16          | 0.001517047                       | 4.3125            | 0.006542265                                      |
| 20          | 0.002938314                       | 3.6               | 0.010577929                                      |
| 24          | 0.001985314                       | 3.916666667       | 0.007775813                                      |
| 28          | 0.002395358                       | 3.785714286       | 0.00906814                                       |
| 32          | 0.002368367                       | 3.59375           | 0.00851132                                       |
| 36          | 0.001769735                       | 3.44444444        | 0.006095754                                      |
| 40          | 0.002005096                       | 3.775             | 0.007569236                                      |
| 44          | 0.002877995                       | 3.454545455       | 0.009942163                                      |
| 48          | 0.002145566                       | 3.375             | 0.007241284                                      |
| 52          | 0.002307235                       | 3.557692308       | 0.008208431                                      |
| 56          | 0.002370425                       | 3.607142857       | 0.008550461                                      |
| 60          | 0.002498435                       | 3.5               | 0.008744522                                      |
| 64          | 0.002004627                       | 3.5625            | 0.007141482                                      |

It can be observed from the above table that clients have re-downloaded the files leading to more than 3 file downloads. Reason for a re-download can be either a lost connection / timeout / no service from server. By multiplying the average file transfer times for each of the cases with the average downloads we can get the average total time each client spend downloading the same 3 files from the server.

We would be plotting this outcome with respect to the number of clients and would be referring to it as 'time to task' to get better visual understanding.

It is observed that the server performed really well at 36 concurrent client connections although the performance was really poor at 8 connections.

In the end, a multithreaded client and multithreaded server implementation was achieved. Even under heavy loads the server performance was consistent with just an average Time To Task deviation of  $\pm$ 0.0025 seconds.
